

# Practice Quiz: Recursion

TOTAL POINTS 5

---

1. What is recursion used for?

1 / 1 point

- ☐ Recursion is used to create loops in languages where other loops are not available.
- ☐ We use recursion only to implement mathematical formulas in code.
- ☐ Recursion is used to iterate through sequences of files and directories.
- ☒ Recursion lets us tackle complex problems by reducing the problem to a simpler one.

**Correct**

You nailed it! By reducing the problem to a smaller one each time a recursive function is called, we can tackle complex problems in simple steps.

2. Which of these activities are good use cases for recursive programs? Check all that apply.

1 / 1 point

- ☒ Going through a file system collecting information related to directories and files.

**Correct**

Right on! Because directories can contain subdirectories that can contain more subdirectories, going through these contents is a good use case for a recursive program.

- ☐ Creating a user account.
- ☐ Installing or upgrading software on the computer.
- ☒ Managing permissions assigned to groups inside a company, when each group can contain both subgroups and users.

**Correct**

You got it! As the groups can contain both groups and users, this is the kind of problem that is a great use case for a recursive solution.

☐ Checking if a computer is connected to the local network.

3. Fill in the blanks to make the `is_power_of` function return whether the number is a power of the given base. Note: base is assumed to be a positive number. Tip: for functions that return a boolean value, you can return the result of a comparison. 1 / 1 point

```
1 def is_power_of(number, base):
2     # Base case: when number is smaller than base.
3     if number < base:
4         # If number is equal to 1, it's a power (base**0).
5         if number == 1:
6             return True
7         return False
8     # Recursive case: keep dividing number by base.
9     return is_power_of(number/base, base)
10
11 print(is_power_of(8,2)) # Should be True
12 print(is_power_of(64,4)) # Should be True
13 print(is power of(70,10)) # Should be False
```

Run

Reset

✓ **Correct**

Nice job! You've made the code check for powers of numbers by reducing the problem to a smaller one.

4. The `count_users` function recursively counts the amount of users that belong to a group in the company system, by going through each of the members of a group and if one of them is a group, recursively calling the function and counting the members. But it has a bug! Can you spot the problem and fix it? 0 / 1 point

```
1 def count_users(group):
2     count = 0
3     for member in get_members(group):
4         count += 1
5         member += 1
6         if is_group(member):
7             count += count_users(member)
8     return count
9
10 print(count_users("sales")) # Should be 3
11 print(count_users("engineering")) # Should be 8
12 print(count_users("everyone")) # Should be 18
```

Run

Reset

! **Incorrect**

Not quite. `count_users("engagement")` returned 10, should be 8. Remember that we want to count the users inside a group, we just don't want to count the groups themselves as users.

5. Implement the `sum_positive_numbers` function, as a recursive function that returns the sum of all positive numbers between the number `n` received and 1. For example, when `n` is 3 it should return  $1+2+3=6$ , and when `n` is 5 it should return  $1+2+3+4+5=15$ .

```
1 def sum_positive_numbers(n):
2     if n < 2:
3         return n
4     return n + sum_positive_numbers(n-1)
5
6 print(sum_positive_numbers(3)) # Should be 6
7 print(sum_positive_numbers(5)) # Should be 15
```

[Run](#)[Reset](#)

**Correct**

Here is your output:

6

15

Great work! You've really nailed writing recursive functions!
